

These are the test result of round 1/5. During the federated learning process, each client trains its own local model on a subset of the data for several epochs. In this case, five clients each trained their model over five epochs, processing small batches of data at each step. The training loss, which measures how far the model's predictions are from the actual labels, started relatively high (around 0.75) and gradually decreased with each epoch. This decline in loss indicates that the models were successfully learning patterns in the data, improving their ability to classify network traffic as either normal or indicative of an attack. After each client completed its local training, the model parameters (weights) from all clients were averaged to create a new, aggregated global model.

Following the aggregation, the updated global model was tested on a separate set of data that the clients had not seen during training. The evaluation showed an average test loss of 0.0090 and an accuracy of 80.83%, meaning the model correctly classified about 81% of the test samples. This result suggests that the federated learning process not only allowed individual clients to learn effectively from their local data but also enabled the global model to generalize well to unseen data. The steady decrease in loss and relatively high test accuracy reflect that the model is performing well at identifying patterns associated with normal and attack traffic across different clients and data splits.

Dataset created and saved to 'network\_traffic.csv'

Training client 1/5 for round 1/5

Client 1, Epoch 1/5, Batch 1, Loss: 0.7557  
Client 1, Epoch 1/5, Batch 2, Loss: 0.7285
